

# **Microphysics Schemes in EMC's Operational Hurricane Models**

**Brad Ferrier, Weiguo Wang, Eric Aligo<sup>1,2</sup>**

<sup>1</sup> Environment Modeling Center (EMC)/NCEP/NWS

<sup>2</sup> I.M. Systems Group, Inc.

**HFIP Physics Workshop**

9 – 11 August 2011

# Complex Production Suite (~2009)

1/4 of Production “Jigsaw Puzzle”

6 Hour Cycle: Four Times/Day

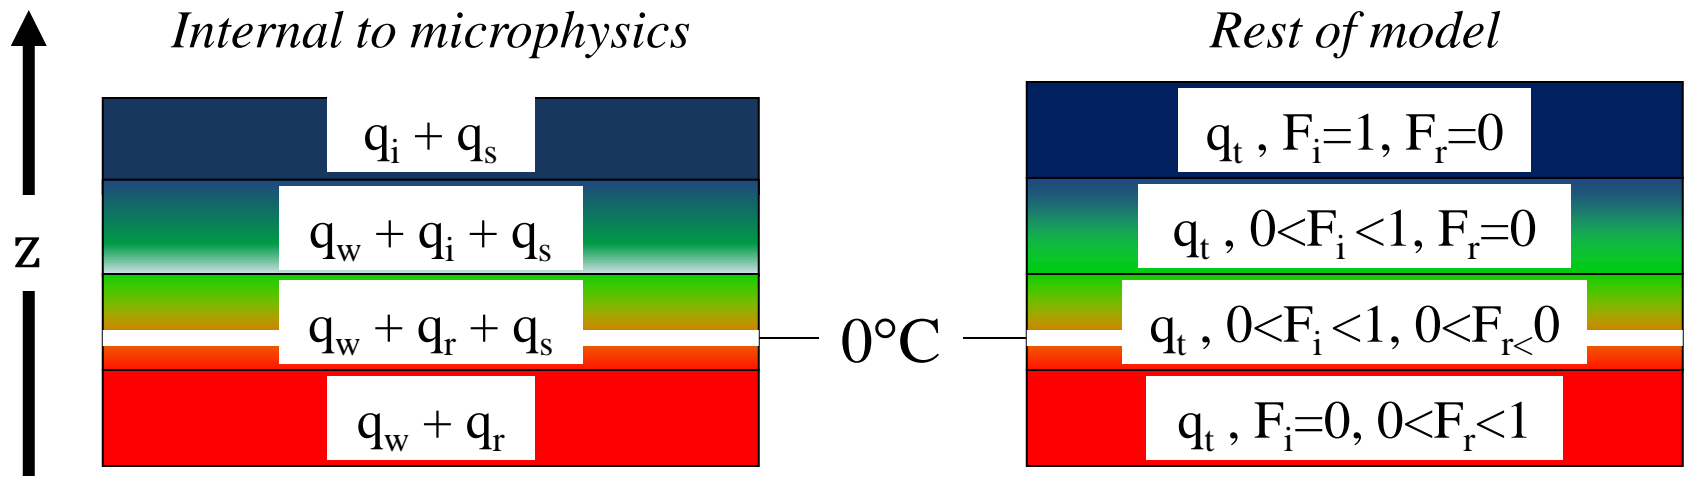

# Microphysics Summary

| Scheme<br>Feature       | Zhao-Moorthi<br>(GFS)  | Ferrier <i>et al.</i> (2002)<br>(GFDL, HWRF, NAM)                               |
|-------------------------|--|---|
| Prognostic variables    | Water vapor, cloud condensate (water or ice)                           | Water vapor, total condensate (cld water, rain, cld ice, "snow")                |
| Condensation algorithm  | Sundqvist <i>et al.</i><br>(RH <sub>c</sub> ~95%, partial clouds)      | Lin <i>et al.</i> , Rutl-Hobbs<br>(target RH ~100%)                             |
| Precip fluxes & storage | Top-down integration of precip, no storage, instantaneous fallout.     | Precip partitioned between storage in grid box & fall out through bottom of box |
| Precipitation type      | Rain, freezing rain, snow  | Rain, freezing rain, snow/graupel/sleet   |
| Mixed-phase conditions  | Liquid or ice (supercooled water & ice do not coexist), simple melting | Mixed-phase as cold as -40 C, more complex melting & freezing processes         |

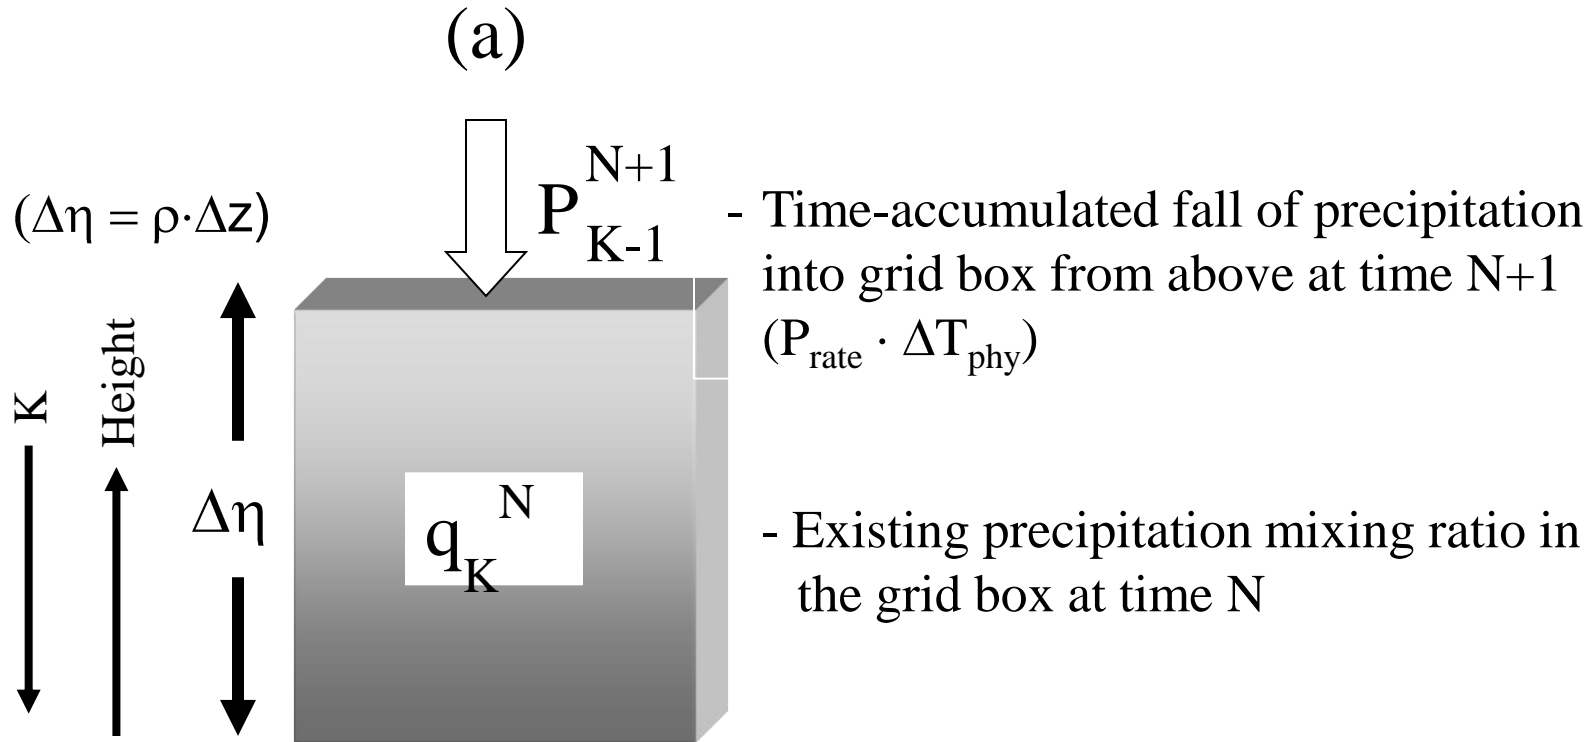

# Advecting Total Condensate (“Ferr”)

- Water vapor ( $q_v$ ), total condensate ( $q_t$ ) advected in model (efficient)
- Cloud water ( $q_w$ ), rain ( $q_r$ ), cloud ice ( $q_i$ ), precip ice ( $q_s$ ) in microphysics
- Arrays store fraction of condensate in form of ice ( $F_i$ ), fraction of liquid in form of rain ( $F_r$ ;  $0 \leq F_i, F_r \leq 1$ ), fixed between microphysics calls.

$$q_t = q_w + q_r + q_i + q_s, \quad q_{\text{ice}} = q_i + q_s \Rightarrow F_i = q_{\text{ice}}/q_t, \quad F_r = q_r/(q_w + q_r)$$

# Precipitation Sedimentation (1 of 3)

(a) Fall of precipitation into grid from above + already existing precipitation

# Precipitation Sedimentation (2 of 3)

(a) Fall of precipitation into grid from above + pre-existing precipitation

(b) Calculate microphysical sources/sinks based on estimate of time-averaged precipitation mixing ratio,  $q_K^{N^*}$

# Precipitation Sedimentation (3 of 3)

- (a) Fall of precip into grid from above + pre-existing precip
- (b) Calculate microphysical sources/sinks based on time-averaged estimate of mixing ratio,  $q_K^{N*}$
- (c) Partition storage ( $q_K^{N+1}$ ) and precipitation through bottom of box ( $P_K^{N+1}$ ) based on thickness of model layer ( $\Delta\eta$ ) & estimated fall distance ( $\Delta t \cdot V_k$ )

# Other Assumptions

- Small cloud ice and large precipitation ice
  - $N_{SI} \sim 10 * N_{LI}$
  - $FLARGE = \text{large} / (\text{small} + \text{large}) \Rightarrow 0.1$  (Hurr),  $0.03$  (NAM)
- Variable density for “snow” (similar to Morrison)
  - 3D rime factor (RF) array for snow/graupel/sleet

$$RF = \frac{\text{Deposition} + \text{Accretion}}{\text{Deposition}}$$

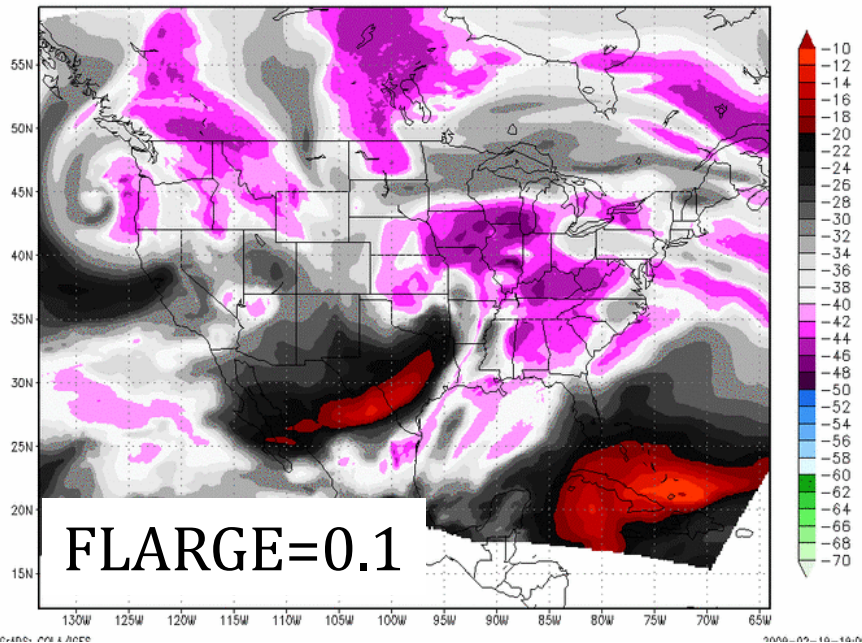

- 1- $\mu\text{m}$  tables for ventilation, accretion, mass, & precipitation rates for liquid drops & ice (fast)

# Forecast satellite products (TOA radiances)

## 3-h NAM forecast water vapor channel 3 (6.5 $\mu\text{m}$ )

2009021109F03 tm00 GOES CH 3 Brightness Temperature

2009021109F03 tm00 GOES CH 3 Brightness Temperature

Less small ice particles,  
warmer  $T_b$ 's (flagged by SPC)

More small ice particles,  
cooler  $T_b$ 's (better)

# First-guess “snow” size (1 of 2)

Assumes (M-P) exponential spectra:

$$N(D) = N_0 \exp(-\lambda \cdot D), \quad [D] = \lambda^{-1},$$

$N_0$  - intercept,  $\lambda$  - slope,  $[D]$  - mean D.

1<sup>st</sup> guess is

$$[D] = D_0 \exp(-0.0536 \cdot T_c),$$

$T_c$  in °C,  $D_0 = 1$  mm. Adjust  $[D]$  so

$$N_{LImin} \leq N_{LI} \leq N_{LImax}$$

HHHP (Washington state)

SMPC (California)

## Based on extratropical stratiform layer clouds

# First-guess “snow” size (2 of 2)

Assumes (M-P) exponential spectra:

$$N(D) = N_0 \exp(-\lambda \cdot D), \quad [D] = \lambda^{-1},$$

$N_0$  - intercept,  $\lambda$  - slope,  $[D]$  - mean D.

1<sup>st</sup> guess is

$$[D] = D_0 \exp(-0.0536 \cdot T_c),$$

$T_c$  in °C,  $D_0 = 1$  mm. Adjust  $[D]$  so

$$N_{LImin} \leq N_{LI} \leq N_{LImax}$$

Should new parameters  
be tested for  
tropical systems?

# My Apologies

*Much of what follows is from  
NMMB model development*

*It is not in the GFDL Hurricane Model,  
in the HWRF model, nor in WRF*

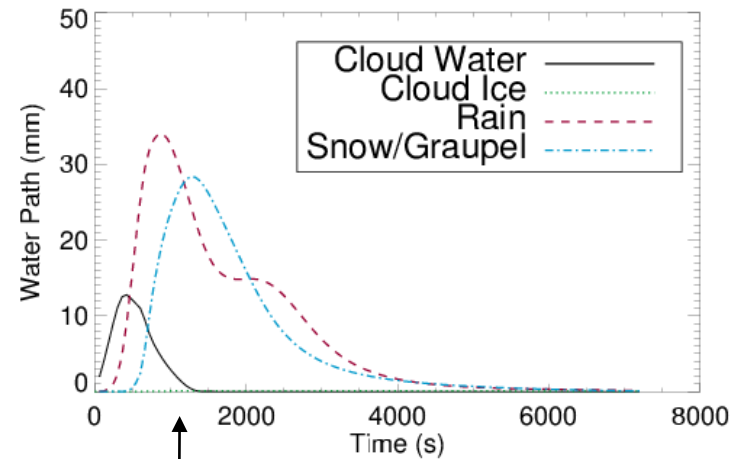

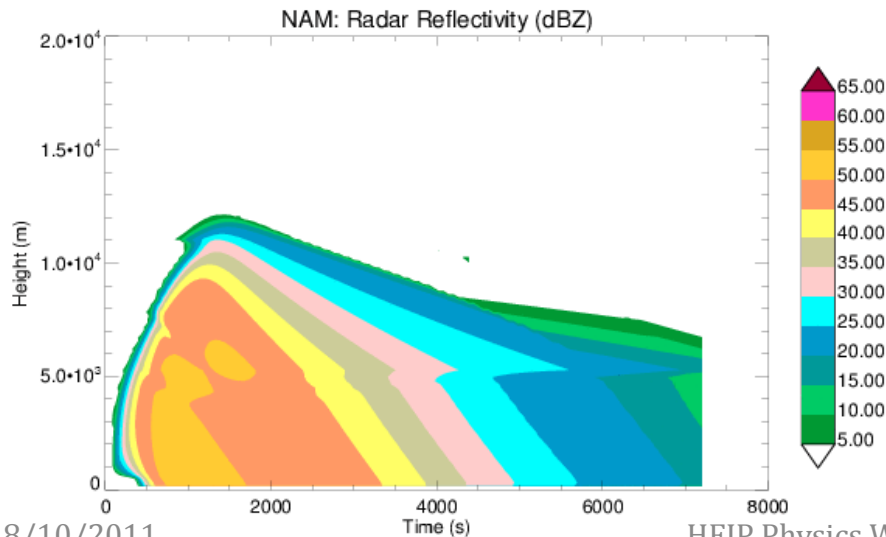

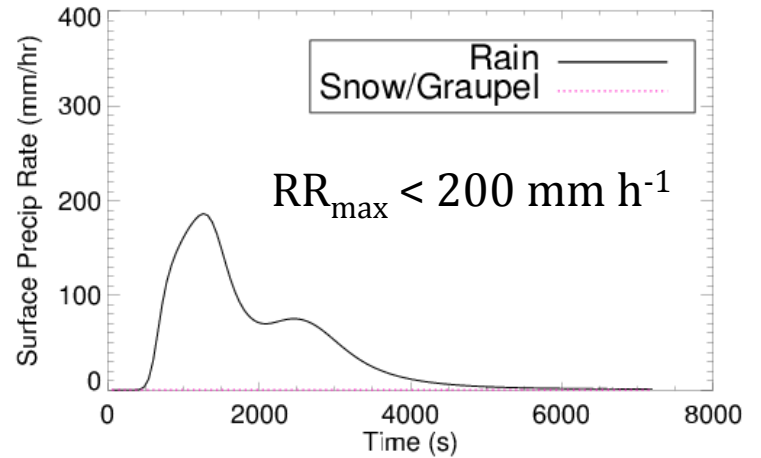

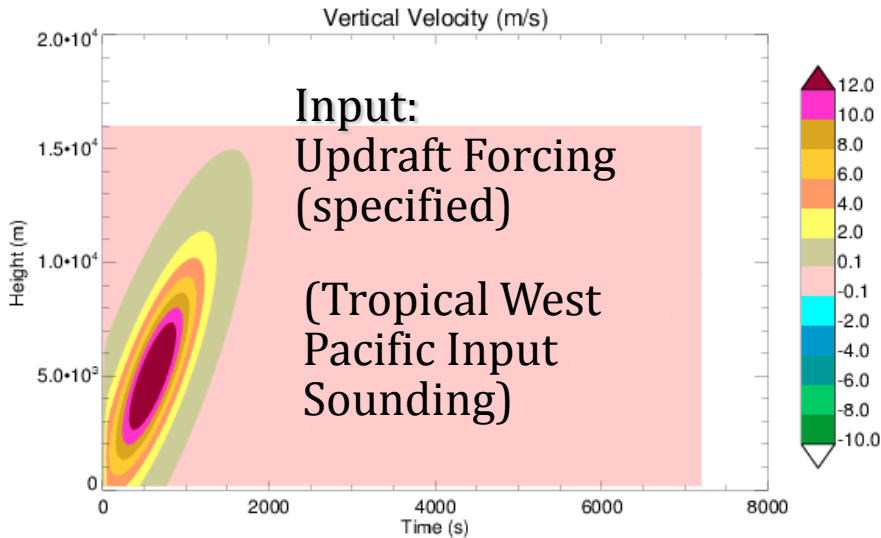

# Recent Activities (NEMS/NMMB)

- Changes in “new” NMMB version of Fer
  - Larger rain drops (expanded rain tables)
  - Allow cloud ice (50  $\mu\text{m}$  crystals) to fall slowly
  - New cloud water to rain autoconversion (Liu & Daum)
  - Faster falling rimed ice ( $\sim V_{\text{RF}}^2$  for  $V_{\text{RF}} > 1$ )
- Flag to control hydrometeor advection
  - Advect  $q_w, q_r, q_i$  or “CWM” only ( $F_i, F_r$ )
  - Applies to all schemes in NMMB (e.g., WSM6, etc)
- Incorporate aspects of GFS/Zhao into Fer?
  - Cloud “macrophysics” for  $>0(10 \text{ km})$  grids

# 1D Column Tests (1 of 3)

Sample 1D input/output (thanks to B. Shipway, UKMO)

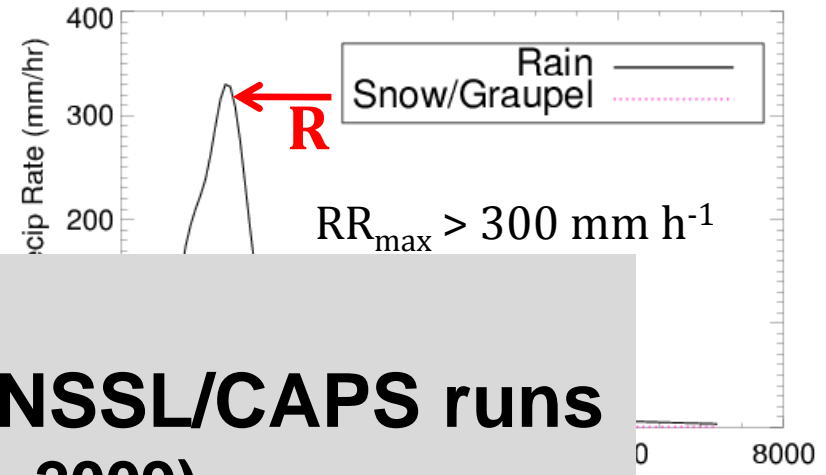

← “Old” NAM Fer

# 1D Column Tests (2 of 3)

## WSM6

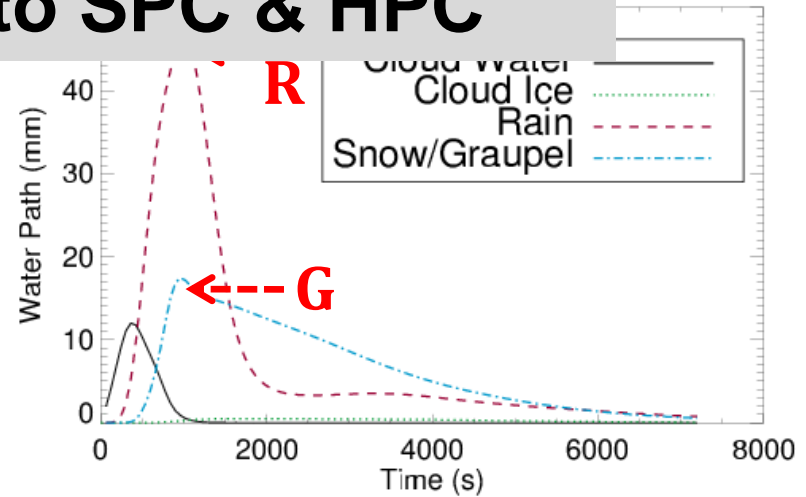

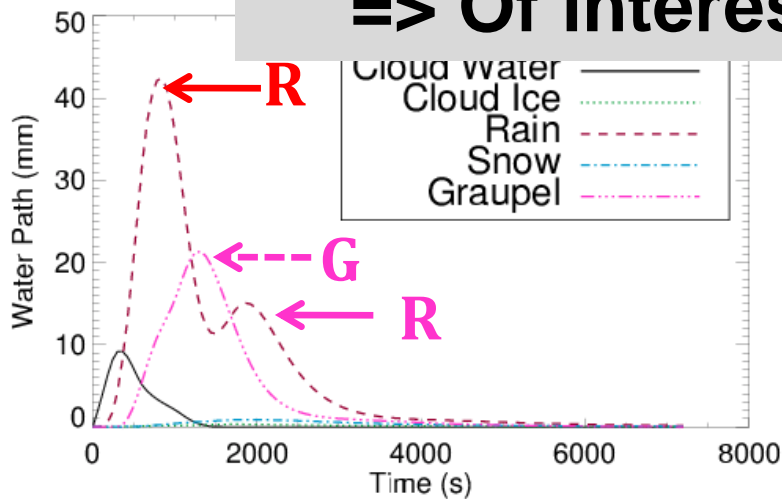

## “New” NMMB fer

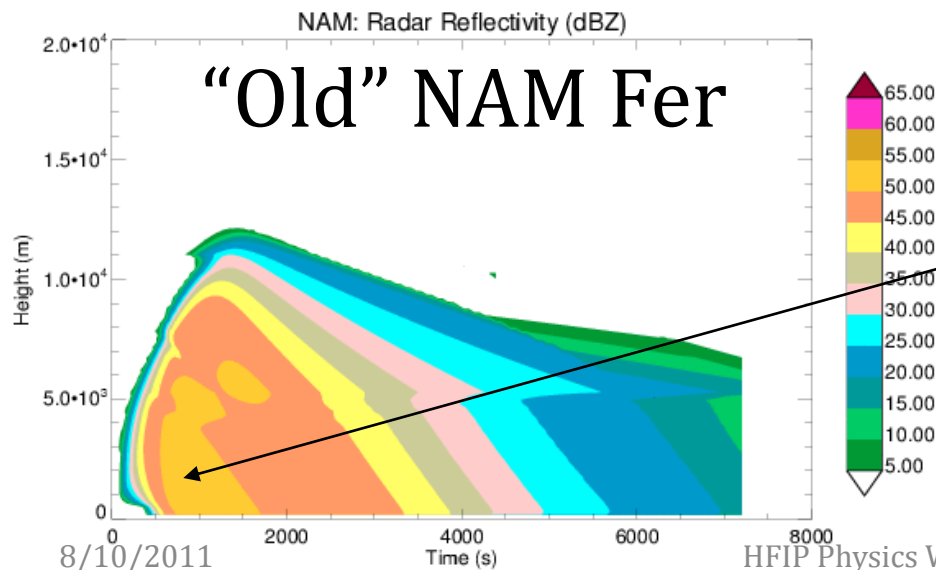

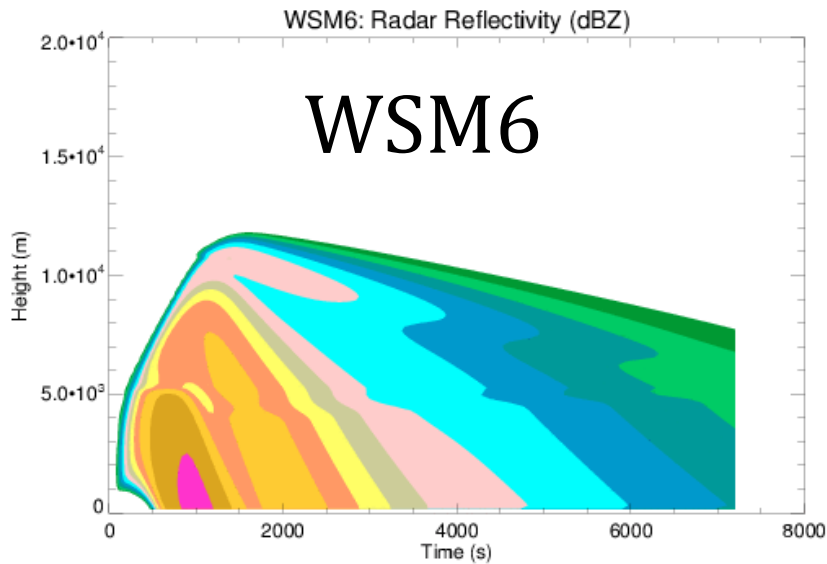

**Q: Why WSM6?**

**A: Used in 4-km NSSL/CAPS runs  
(Kain *et al.*, HPC, 2009)**

**=> Of interest to SPC & HPC**

# 1D Column Tests (3 of 3)

Much higher dBZ & peak rain rates in “New” vs. “Old” Fer

# Impact of microphysics change

## “Old” NAM Fer

COMPOSITE RADAR REFL NEST 09H FCST VALID 09Z 01 MAY 2010

## “New” NMMB Fer

NEST1 COMPOSITE RADAR REFL NEST 09H  
FCST VALID 09Z 01 MAY 2010

- 4-km CONUS nest runs using NMMB
- Higher composite dBZ in revised version (right)

# Scientific Challenges (1 of 2)

- Higher resolution models (inner nests)
  - Depends more on cloud physics details
    - Riming, accretion becomes important (graupel, hail)
    - Different ice habits –  $m(D)$ ,  $V(D)$ , “shape effects”
    - Number concentrations, size spectra of hydrometeors
  - Fundamental aspects of ice still not well known
    - First initiation of ice, ice nucleation at cold temps, **ice enhancement/multiplication** (esp. tropical Cu!)
    - Collection efficiencies between colliding ice species
  - Huge range in costs & complexities of approaches
  - Forecasts often limited by other error sources

# Scientific Challenges (2 of 2)

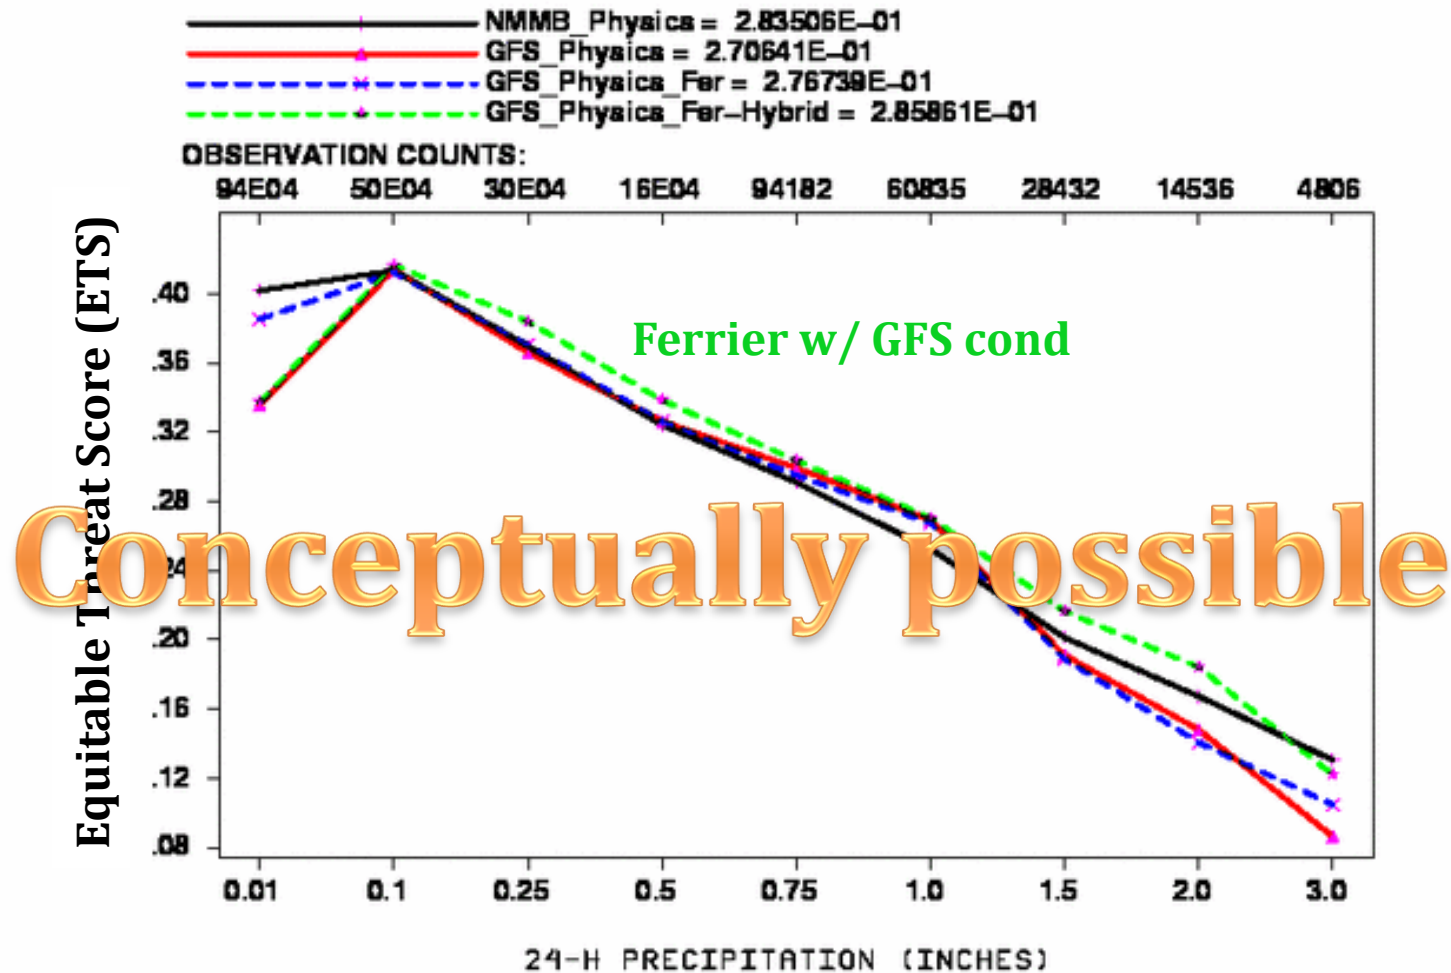

- Coarser grids (outer domain) & subgrid-scale cloud processes
  - Shallow & deep convection
    - Contrasting approaches between modeling groups
    - More interactions w/microphysics for mass flux schemes (e.g., ncloud=1 in SAS)
  - Partial cloudiness, cloud macrophysics
    - GFS/Zhao-Moorthi – uses Sundqvist condensation
    - Validity of collection kernels questionable because of subgrid-scale variability

# Combine NAM & GFS Micro?

- Why?
  - Some NMMB forecasts improved using GFS micro with GFS PBL + SAS
  - Desire for physics unification (S. Lord)
  - Useful for HWRF's outer 27-km domain
  - Sundqvist condensation “responds” to moisture convergence ( $dT/dt$ ,  $dQ/dt$ )
    - $dP/dt=0$ ,  $RH_c=95\%$  rather than 100%
    - Used Sundqvist-based condensation and accretion processes in Ferrier scheme
- Sensitive to proper treatment of detrained condensate from SAS convection ( $ncloud=1$ )

# Preliminary QPF Results (12-km NMMB)

0-84 h Daily Precipitation Verification from 2009012612 to (15 cases)  
2010062012

# Radiation, cloud fractions

- Subtle differences between NAM & HWRF versions of GFDL SW, LW radiation
  - Xu-Randall/Zhao cloud fraction (HWRF) vs PDF-based method (NAM) vs simple method (NMM B)
  - Cloud absorption coefficients (old GFDL radiation units)

|             | HWRF, NAM | Ops NAM | NMMB |
|-------------|-----------|---------|------|
| Cloud Water | 800       | 1600    | 800  |
| Ice         | 500       | 1000    | 500  |

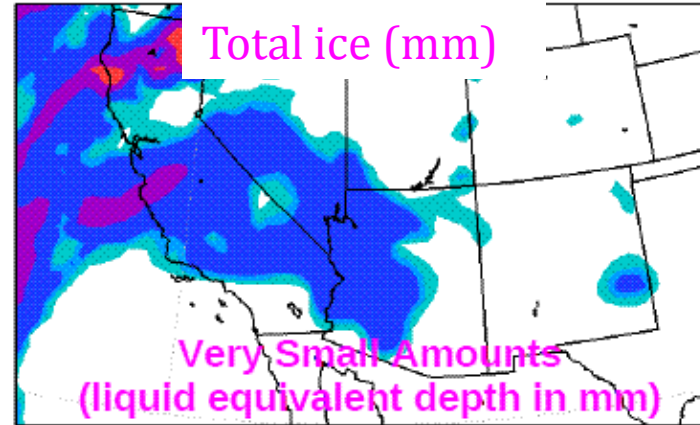

- Larger cloud emissivities in NAM, NMMB
- In WRF/NAM code, LW fluxes are avg of  $T_{\text{skin}} + T_{\text{low}}$  ; also avg'ed LW cooling rates in lowest 2 layers
  - Removed in the operational NAM (March 2008)

# Cloud Fraction Changes (1 of 4)

NAM HIGH CLOUD FRAC nam 33H  
FCST VALID 21Z 04 NOV 2010

NAM TCOL CLDICE+SNOW  
33H FCST VALID 21Z 04 NOV 2010

NAM CLOUD BASE PRES  
33H FCST VALID 21Z 04 NOV 2010

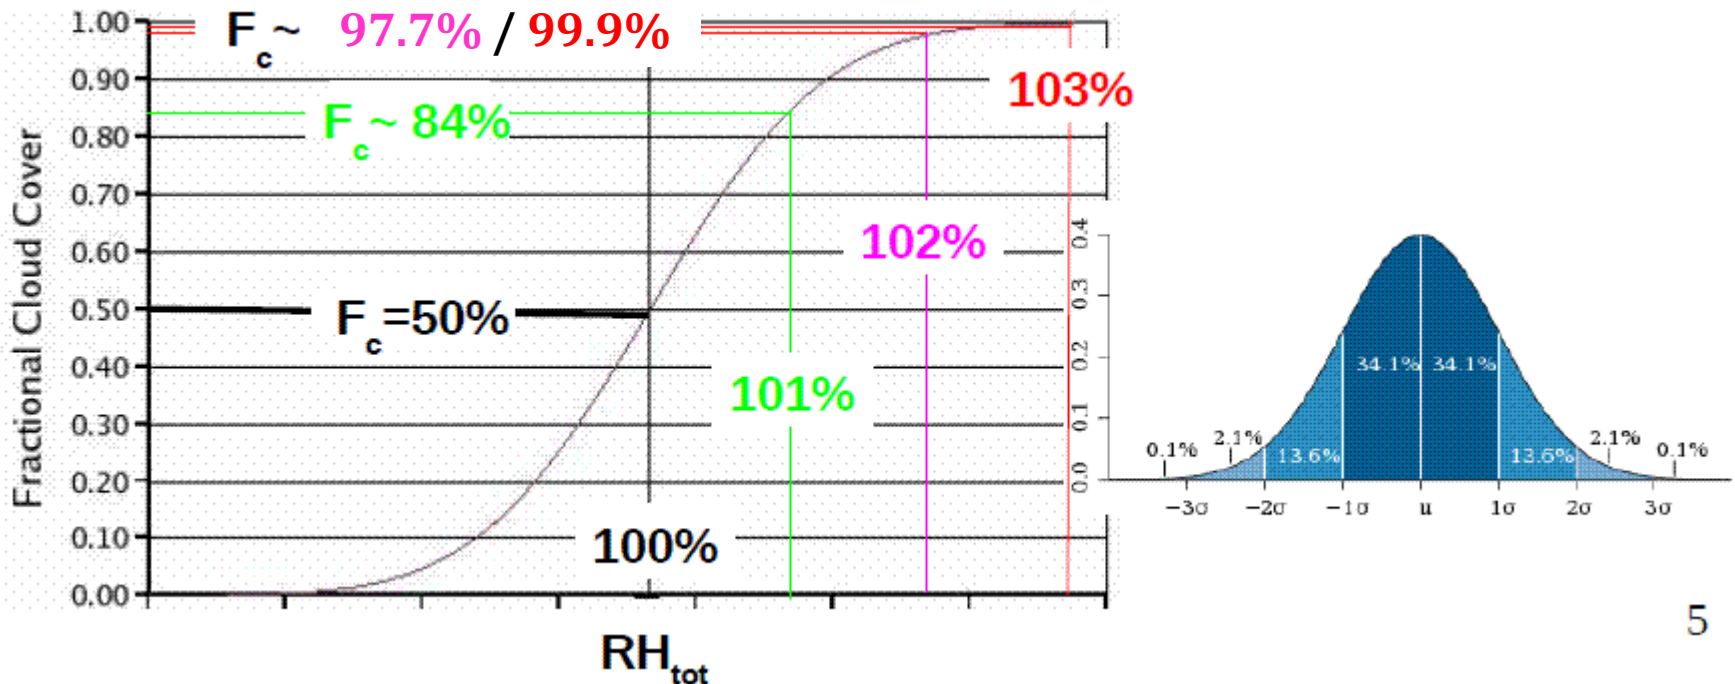

NAM CLOUD TOP PRES  
33H FCST VALID 21Z 04 NOV 2010

The problem: too much overcast from high, very thin cirrus

# Cloud Fraction Changes (2 of 4)

- Total relative humidity,  $RH_{tot} = (Q_v + Q_{cld}) / Q_{sat}$
- Cloud fraction ( $F_c$ ) a function of  $RH_{tot}$ , assumed to be Gaussian with  $\sigma = 1\%$

# Cloud Fraction Changes (3 of 4)

- Cloud water condensation
  - Many CCN, droplet # conc  $O(10^2 - 10^3 \text{ cm}^{-3})$
  - Water supersaturations rarely exceed 1%
- Vapor deposition onto ice
  - Far fewer IN, crystal # conc  $O(1 - 10^3 \text{ L}^{-1})$
  - Much higher  $SS_{\text{ice}}$  at water saturation  
~10% (-10°C), ~21.5% (-20°C), ~34% (-30°C), ~48% (-40°C)
- Ice saturation used for  $Q_{\text{sat}}$  in  $F_c$  at  $T < 0^\circ\text{C}$
- $RH_{\text{tot}} \gg 100\%$  &  $F_c \rightarrow 1$  even when  $Q_{\text{cld}} \rightarrow 0$

# Cloud Fraction Changes (4 of 4)

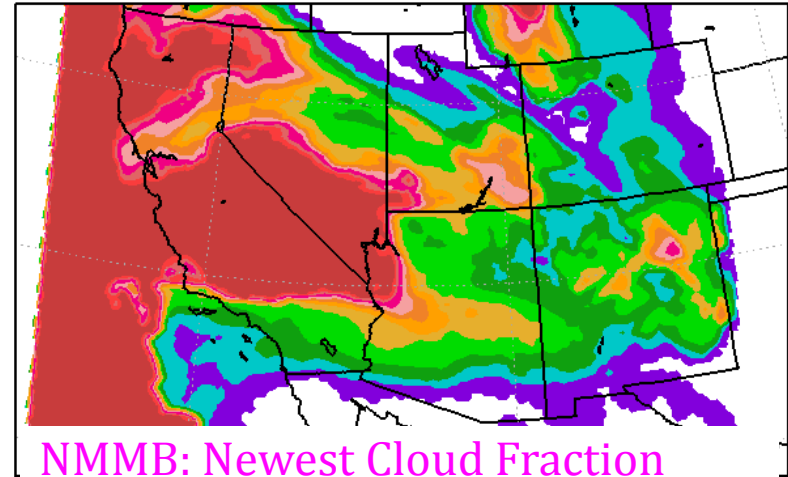

SINGLE\_DOMAIN TOTAL CLOUD FRAC NAM 33H  
FCST VALID 21Z 04 NOV 2010

NAM: Original Cloud Fraction

SINGLE\_DOMAIN TOTAL CLOUD FRAC SWUS 33H  
FCST VALID 21Z 04 NOV 2010

NMMB: Newest Cloud Fraction

**Less upper-level cirrus (right)**

**Simple fix for cloud fraction ( $F_c$ ):**  
$$F_c = \min[1, \text{SQRT}(10^5 * Q_{\text{cld}})]$$

**Better objective verification vs.  
CLAVRx & surface obs (not shown)**

# Community Challenges

- Managing multiple modeling systems (versionitis)
  - HWRF, WRF, & NEMS community codes are complex
  - Connections between physics (“wheel of pain”)
    - e.g. ,  $SW\downarrow_{sfc}$  important for ocean & land models
- Do HWRF movable nest(s) complicate things?
  - Thompson, WSM6 used to work in single domain runs in WRF V2.2
  - Do they work in HWRF V3.3 (e.g. Sam T’s tests)?
- NCEP operations: optimizing costs & benefits
  - Desire for more complex physics - vs - limited computing & human resources
